ABSTRACT

The Hall technique is a novel method of managing carious primary molars by cementing preformed metal crowns, also known as stainless steel crowns (SSCs), over them without local anaesthesia, caries removal or tooth preparation of any kind. Hall technique still has a lot of controversy, so it has not been widely applied in dental practice, especially in Indonesia. This article literature study will compare the strengths and weaknesses of the hall technique from various sides, based on reviews from various sources of research, journals, and textbooks related to the implementation guidelines of hall technique. The advantages of hall technique has been widely recognized by research in developed countries, among others in terms of ease of application, a short processing time, reduce the anxiety level of the patient, and long-term durability when compared with conventional restoration. However, some studies have also found the constraints that can be a debilitating factor of this technique, such as the selection of cases that are less precise and skilled clinicians. However, having the theoretical basis of the application of hall technique is the key to get a successful treatment and minimize the failures that may occur. In conclusion, the development of treatment options for caries in primary teeth, in this case was hall technique, can be considered a treatment option for dental caries performed especially in pediatric dentistry.

Key words: Hall Technique, stainless steel crown, carious primary molar, dental treatment

INTRODUCTION

Percentage of people in Indonesia who have oral and dental problems, according Riskesdas (Riset Kesehatan Dasar), in 2007 to 2013 increased from 23.2% to 35.9%. The latest data in 2013, by age group, the highest proportion of oral and dental problems that are in the productive age range 35-44 years, and is high in children aged 5-9 years in the
